### ABSTRACT

In order to find the susceptibility of the Claisen rearrangement and next proton shift reaction of allyl aryl ether to the substituent effects in para position, the kinetic and thermodynamic parameters are calculated at the B3LYP level using 6-311G\*\* basis set. The calculated activation energies for the rearrangements and proton shift reactions are around 33.33 kcal/mol and 52.16 kcal/mol, respectively. Negative values for the activation entropy confirm the concerted mechanism for the Claisen rearrangement and proton shift reaction. The Hammett  $\rho$  value of -1.3433 obtained in Claisen rearrangement. Negative Hammett  $\rho$  value indicates that the electron donating groups slightly increase the rate of Claisen rearrangement. Positive Hammett  $\rho$  value (2.5132) for proton shift reaction indicates that electron withdrawing groups increase the rate of reaction.

**Keywords:** Hammett; Density functional theory; Substituent effect; Claisen rearrangement; Allyl aryl ether

### INTRODUCTION

A typical organic reaction proceeds in a special mechanism. There maybe several proposed mechanisms for a typical organic reaction. Experimental methods have many instrumental limitations, such as trapping the intermediates or transition states (TSs) in confirming the mechanism that reactions proceed from it. Computational methods can make confirming the mechanism easier, cheaper, and exacter. For example, the gas phase kinetics and the mechanism of two retro-cyclopropane ene reactions were studied by computational methods, therefore, the stepwise mechanism was rejected and the concerted mechanism was fully investigated [1]. Among the most efficient reactions in terms of atom economy are the [3, 3] sigmatropic shifts, that allow the formation of a C-C bond through the rearrangement of the molecule [2]. The [3,3] sigmatropic rearrangement of allyl vinyl ethers,

which allows the preparation of  $\gamma,\delta$ -unsaturated carbonyl compounds, is worthy of study due to its special synthetic relevance as well as the large number of theoretical studies generated. This reaction, first reported by Ludwig Claisen in 1912, [3] was originally described as "the thermal isomerization of an allyl vinyl ether or of its nitrogen or sulfur containing analogue derivatives to afford a bifunctionalized molecule in a  $[\pi^2s + \sigma^2s + \pi^2s]$  process.

The development of the aliphatic Claisen rearrangement was simultaneous with the study of the aromatic version of the reaction [4, 5, 6]. Thus, in the Claisen rearrangement of an allyl aryl ether, the first [3, 3] step affords an ortho dienone which usually enolizes into an o-allylphenol. It is the reaction known as the ortho Claisen rearrangement (Scheme 1).

In the present work we extended our studies to discover the effect of substituent in the rearrangement and 1,3-proton shift reaction of allyl aryl ether by applying the Hammett equation. Eq. (1) shows the basic form of the Hammett equation [7]:

$$\log \frac{k_X}{k_H} = \rho\sigma \quad (1)$$

in which  $k_X$  is the rate constant for a side chain reaction of a benzene derivative where a substituent is in para or meta position with respect to the side chain and  $k_H$  is the corresponding quantity for the unsubstituted compound;  $\sigma$  is a Hammett substituent constant which in principle is characteristic of the substituent, and  $\rho$  is a reaction constant, which depends on the nature of the

reaction. The Hammett equation is an of the important example of linear free energy relationships (LFERs), which widely used in studies of the chemical reactivity of substituted benzenes [8]. Several compilations of the Hammett  $\sigma_p$  and enhanced  $\sigma_p$  ( $\sigma^+$ ) values [9] are tabulated in Table 1.

## COMPUTATIONAL DETAILS

The structures corresponding to the reactants, TSs, intermediates, and products (Scheme 1) were optimized, using the Gaussian 03 computational package [10] with DFT method. The optimized geometries of the stationary points on the potential energy surfaces (PES) were performed using the Becke's three-parameter hybrid exchange functional with the correlation functional of Lee, Yang, and Parr (B3LYP) [11,12] with the 6-311G\*\* basis set. To confirm the nature of the stationary species and evaluate the activation energy barriers, frequency calculations are carried out. For minimum state structures, only real frequency values and for the transition states, only a single imaginary frequency value is accepted. The synchronous transit guided quasi-Newton (STQN) method [13] was used to locate the TSs. The activation energies,  $E_a$  and the Arrhenius factors were computed using Eqs. (2) and (3), respectively, which were derived from the transition state theory [14,15]:

$$E_a = \Delta H^\ddagger(T) + RT \quad (2)$$

$$A = (ek_B T/h) \exp(\Delta S^\ddagger(T)/R) \quad (3)$$

Thermodynamic parameters were calculated at 298.15 K and 1.0 atm.

## RESULTS AND DISCUSSION

Thermodynamic data are presented for allyl aryl ether to their corresponding intermediates (sigmatropic reaction), and for intermediates to corresponding ortho-allylphenols (1,3-proton shift), with different substituent (Scheme 1, Table 2). These are calculated at the B3LYP/6-311G\*\* level, which include: sum of electronic and thermal enthalpies (H), sum of electronic and thermal Gibbs free energies (G), and entropies (S) for the ground state of reactants, products, intermediates, and their corresponding transition states (TS). Using the above data,

the equilibrium constants ( $K_{eq}$ ), Gibbs free energies ( $\Delta G^\ddagger$ ), enthalpies ( $\Delta H^\ddagger$ ), and entropies ( $\Delta S^\ddagger$ ) of reactions for both rearrangement and 1,3-proton shift reaction are calculated and collected in Table 3. The activation energies ( $E_a$ ), rate constants (k), pre exponential factors (A), enthalpies of activation ( $\Delta H^\ddagger$ ), Gibbs activation free energies ( $\Delta G^\ddagger$ ), activation entropies ( $\Delta S^\ddagger$ ),  $\eta_T$  (the position of the transition structure along the reaction coordinate), and  $\log(k_2/k_1)$  for sigmatropic rearrangements and 1,3-proton shift reactions, are presented in Tables 4 and 5.

**Table 2.** Calculated B3LYP/6-311G\*\* thermodynamic data for Claisen rearrangement and next proton shift reaction including: sum of electronic and thermal Gibbs free energies (G), sum of electronic and thermal enthalpies (H), and entropies (S) for the ground state of reactants (R), product (P), intermediates (IM), and their corresponding transition states (TS1 and TS2)

### Kinetic and thermodynamic study

Calculations show that the sigmatropic rearrangements with various substituents are endothermic ( $\Delta H^{\circ} > 0$ ) and the global rearrangement process is not spontaneous ( $\Delta G^{\circ} > 0$ ), on the other hand the proton shift reactions with all studied substituents are exothermic ( $\Delta H^{\circ} < 0$ ) and the global proton shift reactions are spontaneous ( $\Delta G^{\circ} < 0$ ). Our calculated  $\Delta G^{\circ}$  for the sigmatropic rearrangements and proton shift reactions are very similar to their numerically calculated values of  $\Delta H^{\circ}$  (Table 3). As we can see from Table 3, the calculated entropy values are generally small (absolute values of  $\Delta S^{\circ}$  are less than 2.2 cal/mol.K for the rearrangements and 3.7 cal/mol.K for the proton shift reactions). These results indicate that the entropy effect on

the Gibbs free energy is very small and the entropy term and  $T\Delta S^{\circ}$  value can be neglected for the equilibria constant. Thus, the enthalpic term is dominant in the determination of the equilibrium constant. From Tables 4 and 5 we can see that the calculated Gibbs free energy barriers for the sigmatropic rearrangements and proton shift reactions with various substituents are on average 34.08 kcal/mol and 52.22 kcal/mol, respectively, which are very similar to the calculated enthalpy barriers. Activation energies for the rearrangements and proton shift reactions are around 33.33 kcal/mol and 52.16 kcal/mol, respectively. The normal range for the experimental activation energies of Claisen rearrangement with methyl substituent in para position is about 36.08 kcal/mol [1].

### Position of the transition structures

Hammond's postulate can be interpreted in terms of the position of the transition structure along the reaction coordinate,  $n_T$ , (Eq.4) as defined by Agmon [16]:

$$n_T = \frac{1}{2 - (\Delta G^0 / \Delta G^\ddagger)} \quad (4)$$

According to this equation, the position of the transition state along the reaction coordinate is determined solely by  $\Delta G^0$  (a thermodynamic quantity) and  $\Delta G^\ddagger$  (a kinetic quantity). According to Table 4, the values of  $n_T$  for the Claisen rearrangement with various substituent are  $>0.5$  but for the proton shift reaction with various substituents these values are  $<0.5$ . The magnitudes of  $n_T$ , that indicate the degree of similarity between the transition structure and the product, for the rearrangement with electron withdraw substituent are greater than with electron donor substituent, but for the proton shift reaction this conclusion is reversed. This sequence implies that among the transition structures, those in the rearrangement have the largest similarity to the product and in the proton shift reaction have the smaller resemblance to the product.

### Hammett study

Plots of  $\log(k_X/k_H)$  (Tables 4 and 5) vs. Hammett substituent constant for the rearrangement and proton shift reactions are shown in Figs. 1-2. The results of a linear regression for  $\log(k_X/k_H)$  versus Hammett  $\sigma$  constant for the rearrangement and proton shift reaction are given in Eqs. 5 and 6:

$$\log \left( \frac{k_X}{k_H} \right)_{\text{Rearrangement}} = -1.3433\sigma_p + 0.4935 \quad R^2 = 0.7728 \quad (5)$$

$$\log \left( \frac{k_X}{k_H} \right)_{\text{Proton shift}} = 2.5132\sigma_p - 0.5673 \quad R^2 = 0.8911 \quad (6)$$

The Hammett  $\rho$  value of -1.3433 (Fig.1) is obtained for Claisen rearrangement and the correlation coefficient between  $\log(k_X/k_H)$  and  $\sigma_p$  is 0.7728 (Fig.2). Negative Hammett  $\rho$  value indicates that the electron donating groups moderately increase the rate of Claisen rearrangement. Positive Hammett  $\rho$  value (2.5132) for proton shift reaction indicates that the electron withdrawing groups increase the rate of reaction.

### CONCLUSION

DFT calculations portray a clear picture of electronic effect on allyl aryl ether rearrangement and its next step (proton shift reaction). The agreement between the numerical values of  $\log(k_X/k_H)$  and Hammett substituent constant were excellent and Eqs. 5 and 6 describe these relationships. Negative Hammett  $\rho$  value for Claisen rearrangement indicates that the electron donating groups moderately increase the rate of the reaction; on the other hand positive value indicates that the electron withdrawing groups increase the proton shift reaction rate. Considerable deviation of the correlation factor from 1 indicates that the steric parameters could be important in these reactions.

Fig.1. Regression plot between  $\log(k_x/k_H)$  and Hammett substituent constant at the para position ( $\sigma_p$ ) for the Claisen rearrangement.

Fig.2. Regression plot between  $\log(k_x/k_H)$  and Hammett substituent constant at the para position ( $\sigma_p$ ) for the proton shift reaction.
