(Received: 1 January 2019 Accepted: 21 May 2019)

KEYWORDS	ABSTRACT: Lead is a toxic heavy-metal pollutant which is hazardous to human health and the environment. Sodium nitroprusside is commonly used as a nitric oxide donor in plants. Nitric oxide is a bioactive molecule playing an important role in response to stress in plants. Weight, chlorophyll content, and the activity of catalase (EC 1.11.1.6)
Lead; Weight; Chlorophyll; Antioxidant enzymes; Sodium nitroprusside	and peroxidase (EC 1.11.1. 7) antioxidant enzymes of canola (<i>Brassica napus</i> L.) Hyola 401 in lead stress were investigated. This study tested the hypothesis that sodium nitroprusside plays an ameliorating role under lead-toxicity in canola. For seven days, thirteen-day plants were exposed to two levels of sodium nitroprusside (0 and 100 μ M) and three levels of lead (0, 100, and 200 μ M). Dry and fresh weight and chlorophyll content were decreased in lead stress, while sodium nitroprusside treatment increased weight and chlorophyll b in the same conditions. Lead stress increased the activity of antioxidant enzymes, and sodium nitroprusside treatment reduced their activity. The results showed that the use of sodium nitroprusside reduces lead toxicity.

INTRODUCTION

There are several varieties in the Brassicaceae species [1]. Canola (*Brassica napus* L.) can be cultivated in different regions of Iran and is used to produce plant oil [2]. Canola seeds contain 40% oil and 17 to 26 % protein. Most of its proteins include Napin, Cruciferin, and Oleosin. Therefore, canola oil is very useful for human and much effort is needed to cultivate it [3-4].

Heavy metals have a lot of negative effects on canola production [5]. The increasing pollution of the environment with hazardous chemicals, including lead, is extremely dangerous for animals and plants, and as the soil is contaminated, the production decreases [6-7]. Lead has a negative effect on plants, and plants do not need this heavy element. Lead toxicity causes to blockage of enzymes, disturbance in mineral nutrition, disturbance of water balance, changes in hormonal status and permeability of the membrane. The need for more crops, and the use of polluted environment is an important issue [8]. Reactive oxygen species (ROS) and hydrogen peroxide produced in lead stress cause oxidative damage [9-11]. ROS can be very harmful to organisms at high concentrations, although some of them may play a role in regulating gene expression. According to the research report of the geographic region of Golestan province in the Islamic Republic of Iran, heavy metals have an adverse effect and serious environmental consequences [12]. When the lead concentration increased in the shoot of rice, it increased oxidative stress and enhanced lead concentration and time, causing higher levels of stress [13].

High concentrations of heavy metals cause toxic effects such as the reduced height, shoot, and root growth, and

even death of plants [14]. The dangerous concentration of lead in the soil will have serious consequences for plant life and growth [7]. Typically, measurements of chlorophyll content investigate the stress of heavy metals [15-16]. These metals can have a negative and dangerous effect on the plants' growth and the amount of photosynthesis [17]. Photosynthesis breakdown occurs in the stressed substitution of magnesium atoms in the center of chlorophyll by heavy metals such as lead, nickel and mercury, [18].

Under stress conditions, plants use their antioxidant system to neutralize and remove ROS in order to reduce the effects of oxidative stress, with its non-enzymatic defense system using compounds such as the reduced glutathione, vitamin C (ascorbate) and vitamin E (alphatocopherol), and the enzymatic portion includes superoxide dismutase (SOD, EC 1.15.1. 1), catalase (CAT, EC 1.11.1. 6) and peroxidases (POD, EC 1.11.1. 7) [19]. Catalase is an intracellular antioxidant enzyme, which is predominantly present in cell peroxisomes and to some extent, cytosol, and undergoes two stages of hydrogen peroxide reduction to water, and molecular oxygen and catalase are effective in high-intensity stresses. Another part of the hydrogen peroxide removal by peroxidases is located in the cytosol, vacuoles, and cell wall [20]. By increasing or decreasing the activity of antioxidant enzymes in different plants due to a variety of non-biological stresses the oxidative stress levels can be determined [21]. The increased activity of CAT and POD enzymes in lead stress has been reported [22].

In plants, there is a signaling molecule called nitric oxide (NO), which causes various biological functions due to its high diffusibility [23]. NO is a gas-free radical, and its chemistry is intermediate between three species. Sodium nitroprusside (SNP) is used as an antioxidant and plant growth regulator in order to reduce the negative effects caused by various stresses. The effects of SNP (nitric oxide donor) in a variety of abiotic stress in plants, such as salinity and heavy metals, have been shown [24-25]. NO treatment in heavy-metal stress conditions protects the destruction of DNA, prevents cell death, and reduces the effect of oxidative stress [26]. It has been reported that the use of NO causes the plant to be more resistant to lead stress [27].

Considering that even low levels of lead are toxic and dangerous, conducting research in this area is important and necessary [28]. This study was carried out due to the positive effect of SNP on proving the usefulness of SNP in lead contamination conditions to improve chlorophyll content and plant growth by decreasing the activity of antioxidant enzymes.

MATERIAL AND METHODS

Plant growth conditions

Canola seeds of Hyola 401 cultivars used in this study, were obtained from Golestan University of Gorgan, Islamic Republic of Iran. A total of 2.5% sodium hypochlorite solution was used for sterilization of the selected seeds for 20 minutes. The seeds were then washed with distilled water 5-8 times to remove the solution. Seed germination of petri dishes was carried out on a double layer of wet filter paper and inside the incubator in the dark at 25 ° C. The seven-day seedlings were transferred to Hoagland solution containers of 0.5%. The seedlings were exposed to 14-hour light and 10-hour darkness per day and night in the growth chamber in the containers. The temperature within the chamber was 25 $^\circ$ C, and its humidity was 55% at day and 20 $^{\circ}$ C and 70% humidity at night. The reconstitution of the nutrient solution was performed after six days, so that the Hoagland solution with different concentrations of NO from the source of SNP (control and 100 micromoles per liter) and lead from the lead nitrate source $(Pb(NO_3)_2)$ (control, 100 and 200 micromoles per liter) [29] were added to the containers. The collection was done one week later and then the samples were transferred to the laboratory.

Morphological Parameters

Aerial parts and roots were separated and washed. It was kept at 90 $^{\circ}$ C for one day and night, and the weight of dried samples was determined.

The leaves of plants exposed to different concentrations of lead, and NO were carefully separated to be used for research. The samples were mixed and crushed with 80% acetone, kept in the dark overnight and then passed through the filter. Using the spectrophotometer, the absorbance was read at 645, 652, and 663 nanometer wavelengths. Finally, the levels of chlorophyll a and b was measured under different treatments using the following formula [30]:

$$\frac{C \times a \times v}{FW} Mg. g^{1-}Fw$$

C = Concentration of chlorophyll a = Dilution factor

V = The volume of chlorophyll extracts

Fw = Fresh weight

Enzyme Assay

Enzyme extraction

First, extraction solution was prepared with the necessary compounds, including 50 g polyethylene glycol 2000, 2g ascorbic acid, 2 g EDTA-Na₂, 3.8 g borax and 1.2 g tris, and then, distilled water was added to reach a final volume of 100 ml. In the next step, 1g of fresh organ was weighed separately, and the mixture was ground for 30 minutes with the extracted solution. The resulting solution was maintained for one day and night at 4°C. After that, the solution was centrifuged at 4000 g for half an hour. Then the upper clear solution (enzymatic extract) was maintained at 4°C to measure antioxidant enzyme's activity.

Activity of POD

To measure the enzymatic activity, one ml of acetate buffer 0.2 molar at pH = 5 with 0.2 ml of benzidine, soluble in 50 % alcohol 0.01 molar and 0.4 ml of hydrogen peroxide 3% was mixed. 0.1 ml enzyme extracts were added to the mixture. The absorbance changes were measured at 530 nanometer wavelength against the control device, and the enzyme activity was also calculated based on the unit (OD g⁻¹ Fw min⁻¹) [31].

Activity of CAT

Five ml of the mixture containing 1ml of enzymatic extracts was diluted twice for 60 s at 25°C. 300 μ M phosphate buffer and 100 μ M hydrogen peroxide was incubated. To stop the reaction, 10 ml sulfuric acid 2% was added, and then, the remaining hydrogen peroxide was titrated with potassium permanganate solution (0.01 N) for 15 seconds until turned pale purple. Enzyme activity was stopped during control. The enzyme activity was 1 μ M degradation of hydrogen peroxide in 1 minute [32].

Statistical analysis

The canola plant with three replications and random sampling was studied. The mean data were compared using the Duncan method and SPSS software, and the graphs were plotted using Excel. Text results are probable (P), and a significance criterion is $p \le 0.05$.

RESULTS AND DISCUSSION

The Earth and its soil, and the daily produced crops are threatened by the increased risk of heavy-metal inputs that endanger the health and life of creatures [33-34]. Lead reduces the quality of agricultural soils [35]. As ROS is caused by the contamination of land with heavy metals, which are harmful to the plant, the production of antioxidants can help the plant withstand oxidative stress [7]. NO has been introduced over the past two decades as an important contributor to plant resistance to toxic metals and other stresses [36]. The duality feature of NO is that it has different toxic or defensive behaviors under various stresses and is also ROS [37].

According to Tables 1 and 2, after changes in chlorophyll content, dry weight of the aerial parts, and the antioxidant enzyme activity were measured and recorded, no significant effect on SNP treatments was observed, but in other treatments, the results were significant.

Comparison of mean values of fresh and dry weight data (Figures 1-a, 1-b, 1-c, and 1-d) showed that lead toxicity had a high and significant effect on plant weight. As plants are not able to have their normal activity and cannot absorb soil nutrients, there is a decrease in the activity of root and various parts of the plant, which may be due to the toxicity of lead and its damaging effects on the root [5]. Investigating the effect of different concentrations of heavy metals has shown that a lower concentration has a positive effect on the plant and can even help to improve growth, but higher concentrations will damage the growth, and the plant's resistance to toxicity will be reduced [38]. It was observed that SNP could prevent the degradation of the canola plant during lead stress and disrupt its toxicity, and it was found that SNP could have inhibitory effects against the negative effects of lead; and the significant and potent role of NO in plant growth versus lead stress has been proven (Figures 1-a, 1-b, 1-c, and 1-d). Since the seed germinates until it becomes a complete plant, NO has positive effects on plant growth [39].

As the figures 1-e and 1-f show, lead toxicity reduces chlorophyll content. Producing free radicals, lead stress may cause to chlorophyll degradation in the plant, and thus reduce its levels [40]. This reduction has a negative effect on carbon assimilation [41]. As shown in figure 1e, chlorophyll a content is not increased in stresses with SNP treatment. In case of chlorophyll b, it was observed that NO treatment at a concentration of 100 µM lead causes an increase in its content (Figure 1-f). Therefore, the result was the positive effect of NO on biosynthesis and its beneficial role in preventing chlorophyll degradation in lead stress [42]. Usually, the low and high levels of chlorophyll content are directly associated with the amount of iron in the leaves [43]. Due to this relationship, NO increases the transfer of internal iron and homeostasis and thus increases the production of chlorophyll in the chloroplast [44].

It has been said that the activity of antioxidant enzyme increases in plants in lead stress [45]. It has been proved that when lead contamination affected the plant, it increased the activity of POD and higher activity of POD in the shoot control was observed (Figures 2-a and 2-b). One of the known mechanisms of plant protection against stress of heavy metals may be the induction of POD in contaminated plants [46]. It figures 2-a and 2-b shows that the SNP treatment has significantly reduced the POD activity of plants, which have been exposed to lead stress. The reduction of POD percentage to CAT in the root can be considered as one of the possible mechanisms for combating oxidative stress [47]. It is recommended that heavy-metal stress resistant cultivars are used to produce more and better canola and increase plant yield against contamination [48]. The results show that CAT activity of the plant has increased due to the effect of lead stress (Figures 2-c and 2-d). Lead stress significantly increased the activity of CAT compared to canola control. We found that the intensity of CAT activity in lead stress with a concentration of 200 µM was more than 100 µM, and a significant difference were observed. Previously, there has been a report on changes in the activity of CAT enzymes in the shoot rice of seedlings, so that high concentration inhibits and increases its activity [11]. To increase plant compatibility by keeping the concentration of hydrogen peroxide constant, CAT activity is a factor in increasing stress tolerance [9]. The intensity of stress is effective on plant resistance and antioxidant enzyme's performance. The more severe the stress, the lower the activity of the enzymes, and the more the stress is increased by the enzyme's activity, and the further enhance in the plant's adaptability and growth [38]. CAT activity in control plants did not change significantly with sodium nitroprusside treatment. However, in the shoot, plants under the stress of lead reduced the activity of this enzyme (Figures 2-c and 2-d). The application of SNP had no significant effect on the canola root. Recently, the effect of lead and SNP treatment on antioxidant enzyme's activity has been reported [42]. Considering the positive effect of NO on plant resistance after heavy-metal contamination and its protective role, it decreases the amount of hydrogen peroxide and hence decreases the enzymatic activity [49-51]. It is suggested that NO treatment be used to increase the resistance of the plant to the stress of lead and other heavy metals.

0 µM

Lead stress significantly decreased fresh and dry weights. The effects of SNP on canola grown under the lead stress conditions were positive as shown by the increased weights.

Chl a and Chl b content reduced in response to lead stress. The addition of SNP (100 µM), significantly enhanced the chlorophyll b contents in canola plants under 100 µM lead concentration.

Antioxidant enzyme activities were enhanced by the increase of the lead concentration, and the use of SNP caused a reduction in these activities.

 $100 \,\mu M$

Lead concentrations

 $200 \, \mu M$

Application of exogenous SNP increased the plant growth by decreasing antioxidative enzyme activities. Thus, it can be concluded that SNP has ameliorative effects on canola plants grown under lead stress conditions.
