Jacobian Matrix  
Double Direction Method  
Picard-Mann Process

### Abstract

In this article, the improvement of the numerical performance of the iterative scheme presented by Halilu and Waziri (2018) is considered. This is made possible by hybridizing it with Picard-Mann hybrid iterative process. In addition, the step length is calculated using the inexact line search technique. Under the preliminary conditions, the proposed method's global convergence is established. The numerical experiment shown in this paper depicts the efficiency of the proposed method, which improved the results than the double direction method (Halilu & Waziri, 2018), existing in the literature.

## INTRODUCTION

Systems of nonlinear equations usually arise in the areas of human endeavor such as sciences and engineering. Researchers are tasked with developing efficient and robust iterative methods to solve them. Typically, a system of nonlinear equations is represented as

$$F(x) = 0, \quad (1)$$

Where  $F: \mathbb{R}^n \rightarrow \mathbb{R}^n$  is nonlinear map. Throughout this paper, the space  $\mathbb{R}^n$  denote the  $n$ - dimensional real space,  $\|\cdot\|$  is the Euclidean norm and  $F_k = F(x_k)$ . Some iterative approaches for solving these problems include derivative-free methods Halilu & Waziri, 2017, 2018, 2020; Abdullahi, Halilu, & Waziri, 2018), and Newton and quasi-Newton methods (Dennis & Schnabel, 1983; Waziri, Leong, & Hassan, 2011; Yuan & Lu, 2008). However, Newton's method is prominent due to its attractive features, such as easy implementation and rapid convergence. However, the method requires the computation as well as storage of Jacobian matrix at each iteration and generates a sequence of points using the recursive formula:

$$x_{k+1} = x_k + s_k, \quad s_k = \alpha_k d_k, \quad k = 0, 1, \dots, \quad (2)$$

where  $s_k = x_{k+1} - x_k$  and  $\alpha_k$  is a step length. The Newton's search direction  $d_k$  is determined by solving the following linear system of equations,

$$F_k + F'_k d_k = 0, \quad (3)$$

where,  $F'_k$  is the Jacobian matrix of  $F$  at  $x_k$ . However, in Newton's method, the derivative  $F'$  is computed at each iteration, which may be unavailable or could not be obtained precisely. In this case, Newton's method cannot be applied directly. For this reason, quasi-Newton's methods were developed to replace the Jacobian matrix or its inverse with an approximation which can be updated at each iteration (Yuan & Lu, 2008; Li &

Fukushima, 1999), and its search direction is given by

$$d_k = -B_k^{-1} F_k, \quad (4)$$

where  $B_k$  is  $n \times n$  matrix that approximate the Jacobian of  $F$  at  $x_k$ . Moreover, (1) can be obtained from an unconstrained optimization problem (Fukishima, 1999). Suppose  $f$  be a merit function defined by

$$f(x) = \frac{1}{2} \|F(x)\|^2. \quad (5)$$

Then the problem of nonlinear equations (1) is analogous to the following problem of global optimization

$$\min f(x), \quad x \in \mathbb{R}^n, \quad f: \mathbb{R}^n \rightarrow \mathbb{R},$$

Newton and quasi-Newton's methods require the computation of the Jacobian matrix or its approximation at each iteration, despite the attractive characteristics of these methods. Therefore, they are not ideal for solving large-scale problems because they require massive matrix storage at each iteration which is costly in numerical experiments. Matrix-free methods are proposed to overcome these problems. The double direction method is among the successful matrix-free methods (Petrovic & Stanimirovic, 2014), that generates a sequence of iterates via

$$x_{k+1} = x_k + \alpha_k d_k + \alpha_k^2 b_k, \quad (6)$$

where  $x_{k+1}$  is the current iterate,  $x_k$  is the previous iterate, while  $b_k$  and  $d_k$  are search directions respectively. The rationale behind double direction method is that, there are two corrections in the scheme (6), if one correction fails during iterative process then the second one will correct the system.

In 2014, Petrovic and Stanimirovic proposed a double direction method for solving unconstrained optimization problems. In their work, an approximation to Hessian matrix is obtained via acceleration parameter  $\gamma_k > 0$ , i.e.,

$$\nabla^2 f(x_k) \approx \gamma_k I,$$

where  $I$  is an identity matrix. The sequence of iterates is generated using (6).

$\{x_k\}$  Petrovic (2015) further improves the performance of double direction, where the double step length scheme for the unconstrained optimization problem is presented as:

$$x_{k+1} = x_k + \alpha_k d_k + \beta_k b_k, \quad (7)$$

where,  $\alpha_k$  and  $\beta_k$  are two different step lengths. The Numerical results reported in Petrovic (2015) have shown that the proposed method is quite effective compared to the double direction method in Petrovic and Stanimirovic (2014). Because it has the number of iterations and CPU time than the compared method (Petrovic & Stanimirovic, 2014). Moreover, to improve the convergence properties and numerical results of the double direction methods, Petrovic et al. (2018) hybridized the double direction method for unconstrained optimization problem in (Petrovic & Stanimirovic, 2014), with Picard-Mann hybrid iterative process proposed by Khan in Safeer (2013). The Picard-Mann hybrid iterative process is defined as three relations:

**Definition 1.** The Picard-Mann hybrid iterative process is defined as three relations:

$$x_1 = x \in \mathbb{R}^n, \quad (8)$$

$$y_k = (1 - \eta_k)x_k + \eta_k T x_k, \quad (9)$$

$$x_{k+1} = T y_k, \quad k \in \mathbb{N}, \quad (10)$$

where  $T: \Omega \rightarrow \Omega$  is a mapping defined on nonempty convex subset  $\Omega$  of a normed space  $E$ ,  $y_k$  and  $x_k$  are sequences determined by the iterations in (9) and (10), and is the sequence of  $\{\eta_k\}$  positive numbers in  $(0,1)$ .

In this paper,  $\eta_k$  denotes the correction parameter. Since the research of derivative-free double direction methods for solving systems of nonlinear equations is scarce in the literature, this motivated Halilu and Waziri (2018) to use the scheme in (6) and proposed a derivative-free method via double direction

approach for solving system of nonlinear equations. The method is proved to be globally convergent by assuming that the Jacobian of  $F$  is bounded and positive definite. Abdullahi et al. [9] further improved the performance of the double direction scheme where they modified the idea in Halilu and Waziri (2018) based on conjugate gradient approach to solve symmetric nonlinear equations. The method converged globally using the derivative-free line search proposed by Li and Fukushima in (Li & Fukushima, 1999). Recently, Halilu and Waziri (2020) solved the system of nonlinear equations by improving the double direction iteration approach in (6). The global convergence of the method was established under some mild conditions, and the numerical experiments demonstrated in the paper showed that the proposed method is very efficient.

Motivated by the hybridization method presented in Petrovic et al. (2018), This article is aimed at

hybridizing the double direction method in Halilu and Waziri (2018) with the Picard-Mann hybrid iterative process proposed by Khan (2013). The paper is organized as follows. In the next section, we will present the algorithm of the proposed method. Section 3 presents the proposed algorithm's convergence analysis. Section 4 lists some numerical experiments. The article concluded in section 4.

## MAIN RESULT

Let us consider the derivative-free double direction method in Halilu and Waziri (2018). The method developed a derivative-free method for solving systems of nonlinear equations via

$$F'_k \approx \gamma_k I, \quad (11)$$

where  $I$  is an identity matrix and  $\gamma_k > 0$  is an acceleration parameter. The method in Halilu and Waziri (2018) produces a sequence of

iterates  $x_k$  such that  $x_{k+1} = x_k + s_k$ , where  $s_k + (\alpha_k + \alpha_k^2 \gamma_k) d_k$  and the direction  $d_k$  is given as

$$d_k = -\gamma_k^{-1} F_k. \quad (12)$$

The acceleration parameter is obtained by using first-order Taylor's expansion as

$$\gamma_{k+1} = \frac{y_k^T y_k}{(\alpha_k + \alpha_k^2 \gamma_k) y_k^T d_k}, \quad (13)$$

where  $y_{k-1} = F_k - F_{k-1}$ .

Although the method of Halilu and Waziri (2018) has strong convergence properties, its numerical performance is weak when  $\gamma_k$  approaches or is equal to 1. For this reason, we are motivated to propose a hybrid method with good numerical results. To define a hybrid form of the method in Petrovic (2014), the mapping  $T$  in definition (1) is assumed to

be defined by an improved double direction method as  $Ty_k = y_k - (\alpha_k + \alpha_k^2 \gamma_k) \gamma_k^{-1} F_k$ . By this assumption and the definition (1) we have

$$x_1 = x \in \mathbb{R}^n,$$

$$y_k = (1 - \eta_k)x_k + \eta_k T x_k = x_k - (\eta_k + 1)(\alpha_k + \alpha_k^2 \gamma_k) \gamma_k^{-1} F_k, \quad (14)$$

$$x_{k+1} = T y_k = y_k - (\alpha_k + \alpha_k^2 \gamma_k) \gamma_k^{-1} F_k, \quad k \in \mathbb{N}. \quad (15)$$

From (14) and (15) we obtain the iterative scheme,

$$x_{k+1} = x_k - t_k (\alpha_k + \alpha_k^2 \gamma_k) \gamma_k^{-1} F_k, \quad (16)$$

where,  $t_k = (\eta_k + 1) \in (1, 2)$  is a correction parameter. we can easily show that, the search direction in (16) is defined as

$$d_k = -t_k \gamma_k^{-1} F_k. \quad (17)$$

Next, the proposed method algorithm is specified as follows:

---

**Algorithm 1:** hybrid double direction method (HDDPM)

---

**Input:** Given  $x_0$ ,  $\gamma_0 = 1$ ,  $\epsilon = 10^{-5}$ ,  $\omega_1 > 0$ ,  $\omega_2 > 0$  and  $r \in (0, 1)$ ,  $t \in (1, 2)$ , set  $k = 0$ .

**Step 1:** Compute  $F_k$ .

**Step 2:** If  $\|F_k\| \leq \epsilon$  then stop; otherwise, proceed to Step 3.

**Step 3:** Compute search direction  $d_k = -t \gamma_k^{-1} F_k$ .

**Step 4:** Set  $x_{k+1} = x_k + (\alpha_k + \alpha_k^2 \gamma_k) d_k$ , where,  $\alpha_k = r^{m_k}$  with  $m_k$  being the smallest nonnegative integer  $m$  such that

$$f(x_k + (\alpha_k + \alpha_k^2 \gamma_k) d_k) - f(x_k) \leq -\omega_1 \|\alpha_k F_k\|^2 - \omega_2 \|\alpha_k d_k\|^2 + \eta_k f(x_k). \quad (18)$$

Let  $\{\eta_k\}$  be a given positive sequence such that

$$\sum_{k=0}^{\infty} \eta_k < \eta < \infty. \quad (19)$$

**Step 5:** Compute  $F_{k+1}$ .

**Step 6:** Determine  $\gamma_{k+1} = \frac{y_k^T y_k}{(\alpha_k + \alpha_k^2 \gamma_k) y_k^T d_k}$ .

**Step 7:** Consider  $k = k + 1$  and go to Step 2.

---

## CONVERGENCE

**Analysis** We present how the proposed Algorithm 1 (HDDPM) converges globally in

this section. To begin, let's define the level set.

$$\Omega = \{x \mid \|F(x)\| \leq \|F(x_0)\|\}. \quad (20)$$

Assumption 3.1 However, we state the following assumptions:

1. There exists  $x^* \in \mathbb{R}^n$  such that  $F(x^*) = 0$ .
2.  $F$  is continuously differentiable in some neighborhood say  $Q$  of  $x^*$  containing  $\Omega$ .
3. The Jacobian of  $F$  is bounded and positive definite on  $Q$ . i.e., there exist positive constants  $H > h > 0$  such that

$$\|F'(x)\| \leq H \quad \forall x \in Q, \quad (21)$$

and

$$h\|d\|^2 \leq d^T F'(x)d \quad \forall x \in Q, d \in \mathbb{R}^n. \quad (22)$$

**Remark 2.** We make the following remark: Assumption 3.1 implies that there exist constants  $H > h > 0$  such that

$$h\|d\| \leq \|F'(x)d\| \leq H\|d\| \quad \forall x \in Q, d \in \mathbb{R}^n. \quad (23)$$

$$h\|x - y\| \leq \|F(x) - F(y)\| \leq H\|x - y\| \quad \forall x, y \in Q. \quad (24)$$

Since  $t^{-1} \gamma_k I$  approximates  $F'_k$  along  $s_k$ , the following assumption can be made.

Assumption 3.3  $t^{-1} \gamma_k I$  is a good approximation to  $F'_k$ , i.e.,

$$\|(F'_k - t^{-1} \gamma_k I)d_k\| \leq \epsilon \|F_k\|, \quad (25)$$

where,  $\epsilon \in (0, 1)$  is a small quantity [4].

**Lemma 4.** Suppose Assumption 3.3 holds, and let  $x_k$  be generated by Algorithm 1. Then  $d_k \in \{x_k\}$  is a sufficient descent direction for  $f(x_k)$  at  $x_k$  i.e.,

$$\nabla f(x_k)^T d_k < c \|F_k\|^2, \quad c > 0. \quad (26)$$

**Proof.** From (5), (12), and (25), we have

$$\begin{aligned} \nabla f(x_k)^T d_k &= F_k^T F'_k d_k \\ &= F_k^T [(F'_k - t^{-1} \gamma_k I)d_k - F_k] \\ &= F_k^T (F'_k - t^{-1} \gamma_k I)d_k - \|F_k\|^2, \end{aligned} \quad (27)$$

by Cauchy-Schwarz we have,

$$\begin{aligned} \nabla f(x_k)^T d_k &\leq \|F_k\| \|(F'_k - t^{-1} \gamma_k I)d_k\| - \|F_k\|^2 \\ &\leq -(1 - \epsilon) \|F_k\|^2. \end{aligned} \quad (28)$$

Since  $\epsilon \in (0, 1)$ , taking  $c = 1 - \epsilon$ , this lemma is true.

We can conclude from Lemma 3.4 that the norm function  $f(x_k)$  is a descent along  $k$ , which means that  $\|F_{k+1}\| \leq \|F_k\|$  is true. ■

**Lemma 5.** Suppose that Assumption 3.1 holds and let  $\{x_k\}$  be generated by Algorithm 1. Then  $\{x_k\} \subset \Omega$ .

**Proof.** From Lemma 3.4, we have  $\|F_{k+1}\| \leq \|F_k\|$ . Furthermore, for all  $k$ ,  $\|F_{k+1}\| \leq \|F_k\| \leq \|F_{k-1}\| \leq \dots \leq \|F_0\|$ .

This means that  $\{x_k\} \subset \Omega$ . ■

**Lemma 6.** Suppose Assumption 3.1 holds and  $\{x_k\}$  be generated by Algorithm 1. Then there exists a constant  $m > 0$  such that for all  $k$ ,

$$y_k^T s_k \geq h \|s_k\|^2. \quad (29)$$

**Proof.** By mean-value theorem and (22),

$$y_k^T s_k = s_k^T (F(x_{k+1}) - F(x_k)) = s_k^T F'(\xi) s_k \geq h \|s_k\|^2.$$

Where  $\xi = x_k + \zeta(x_{k+1} - x_k)$ ,  $\zeta \in (0, 1)$ .

Using  $y_k^T s_k \geq h \|s_k\|^2 > 0$ ,  $\gamma_{k+1}$  is always generated by the update formula (??). herefore,  $\gamma_{k+1}$  inherits the positive definiteness of  $\gamma_k$ . From Lemma 3 and (??), the following inequality holds.

$$\frac{y_k^T s_k}{\|s_k\|^2} \geq h, \quad \frac{\|y_k\|^2}{y_k^T s_k} \leq \frac{H^2}{h}. \quad (30)$$

**Lemma 7.** Suppose that Assumption 3.1 holds and  $\{x_k\}$  is generated by Algorithm 1. Then we have

$$\lim_{k \rightarrow \infty} \|\alpha_k d_k\| = 0, \quad (31)$$

and

$$\lim_{k \rightarrow \infty} \|\alpha_k F_k\| = 0. \quad (32)$$

**Proof.** From (18) for all  $k > 0$

$$\begin{aligned} \omega_2 \|\alpha_k d_k\|^2 &\leq \omega_1 \|\alpha_k F_k\|^2 + \omega_2 \|\alpha_k d_k\|^2 \\ &\leq \|F_k\|^2 - \|F_{k+1}\|^2 + \eta_k \|F_k\|^2. \end{aligned} \quad (33)$$

By summing the above inequality, we have

$$\begin{aligned}
 \omega_2 \sum_{i=0}^k \|\alpha_i d_i\|^2 &\leq \sum_{i=0}^k (\|F_i\|^2 - \|F_{i+1}\|^2) + \sum_{i=0}^k \eta_i \|F_i\|^2, \\
 &= \|F_0\|^2 - \|F_{k+1}\|^2 + \sum_{i=0}^k \eta_i \|F_i\|^2, \\
 &\leq \|F_0\|^2 + \|F_0\|^2 \sum_{i=0}^k \eta_i, \\
 &\leq \|F_0\|^2 + \|F_0\|^2 \sum_{i=0}^{\infty} \eta_i.
 \end{aligned} \tag{34}$$

From the level set and the fact that  $\{\eta_k\}$

satisfies (19), then the series  $\sum_{i=0}^{\infty} \|\alpha_i d_i\|^2$

This implies (31). Using the same logic as above, but this time with  $\omega_1 \|\alpha_k F_k\|^2$  on the left, we obtain (32).

**Lemma 8.** Suppose Assumption 3.1 holds and let  $\{x_k\}$  be generated by Algorithm 1. Then there exists a constant  $M > 0$  such that for all  $k > 0$ , **Proof.** From (12) and (13) we have

$$\|d_k\| \leq M. \tag{35}$$

**Proof** From (12) and (13) we have

$$\begin{aligned}
 \|d_k\| &= \left\| -t \frac{(\alpha_{k-1} + \alpha_{k-1}^2 \gamma_{k-1}) y_k^T d_k}{y_{k-1}^T y_{k-1}} \right\| \\
 &= \left\| -\theta \frac{y_{k-1}^T s_{k-1} F_k}{\|y_{k-1}\|^2} \right\| \\
 &\leq \frac{t \|F_k\| \|s_{k-1}\| \|y_{k-1}\|}{h^2 \|s_{k-1}\|^2} \\
 &\leq \frac{t \|F_k\| H \|s_{k-1}\|}{h^2 \|s_{k-1}\|} \\
 &\leq \frac{t \|F_k\| H}{h^2} \\
 &\leq \frac{t \|F_0\| H}{h^2}.
 \end{aligned}$$

Taking  $M = \frac{t \|F_0\| H}{h^2}$ , we have (35).

**Theorem 9.** Suppose that Assumption 3.1 holds and  $\{x_k\}$  be generated by Algorithm 1. Assume further for all  $k > 0$ ,

$$\alpha_k \geq \lambda \frac{|F_k^T d_k|}{\|d_k\|^2}, \tag{37}$$

where  $\lambda$  is some positive constant. Then

$$\lim_{k \rightarrow \infty} \|F_k\| = 0. \tag{38}$$

**Proof.** From Lemma 8 we have (35). Also, from (31) and the boundedness of  $\{\|d_k\|\}$ , we have

$$\lim_{k \rightarrow \infty} \alpha_k \|d_k\|^2 = 0, \tag{39}$$

from (37) and (39) we have

$$\lim_{k \rightarrow \infty} |F_k^T d_k| = 0. \tag{40}$$

Also, from (12) we have,

$$F_k^T d_k = -t \gamma_k^{-1} \|F_k\|^2, \tag{41}$$

$$\begin{aligned}
 \|F_k\|^2 &= | -F_k^T d_k t^{-1} \gamma_k | \\
 &\leq t^{-1} |\gamma_k| |F_k^T d_k|.
 \end{aligned} \tag{42}$$

Since

$$\begin{aligned}
 \gamma_k^{-1} &= \frac{(\alpha_{k-1} + \alpha_{k-1}^2 \gamma_{k-1}) y_k^T d_k}{y_{k-1}^T y_{k-1}} = \frac{y_{k-1}^T s_{k-1}}{\|y_{k-1}\|^2} \\
 &\geq \frac{h \|s_{k-1}\|^2}{\|y_{k-1}\|^2} \geq \frac{h \|s_{k-1}\|^2}{H^2 \|s_{k-1}\|^2} = \frac{h}{H^2}.
 \end{aligned}$$

Then,

$$|\gamma_k^{-1}| \geq \frac{h}{H^2}.$$

Therefore, from (42) we have,

$$\|F_k\|^2 \leq |F_k^T d_k| \left( \frac{H^2}{th} \right). \tag{43}$$

As a result,

$$0 \leq \|F_k\|^2 \leq |F_k^T d_k| \left( \frac{H^2}{th} \right) \rightarrow 0. \tag{44}$$

Hence,

$$\lim_{k \rightarrow \infty} \|F_k\| = 0. \tag{45}$$

The proof is completed.

## NUMERICAL EXPERIMENTS

In this section, we test the efficiency and robustness of our proposed method (HDDPM) using the following existing methods in the literature:

- An improved derivative-free method via double direction approach for solving

systems of nonlinear equations (IDFDD) (Halilu and Waziri, 2018).

The computer codes utilized were written in Matlab 9.4.0 (R2018a) and run on a personal computer equipped with a 1.80 GHz CPU processor and 8 GB RAM. The two algorithms were implemented with the same line search (18) in the experiments, and the following parameters are set:  $\omega 1 = \omega 2 = 10^{-4}$ ,  $r = 0.2$ , and  $\eta_k = 1/(k+1)^2$ , as they are taken in [5]. We, however, set  $t = 1.2$  in our algorithm. The program execution is stopped if the total number of iterations exceeds 1000 or  $5 \parallel F_k \parallel 10^{-5} \leq$ . To show the extensive numerical experiments of HDDPM and DFDD methods, we have tried these methods on the previous three Benchmark test problems with different initial points and dimensions (n values) between 1000 and 100,000.

**Problem 1** [7]

$$F_i(x) = (1 - x_i^2) + x_i(1 + x_i x_{n-2} x_{n-1} x_n) - 2, \quad i = 1, 2, \dots, n.$$

**Problem 2** [5]

$$F_i(x) = x_i - 3x_i \left( \frac{\sin x_i}{3} - 0.66 \right) + 2, \quad i = 1, 2, \dots, n.$$

**Problem 3** [8]

$$\begin{aligned} F_1 &= x_1 - e^{\cos\left(\frac{x_1+x_2}{n+1}\right)}, \\ F_i &= x_i - e^{\cos\left(\frac{x_{i-1}+x_i+x_{i+1}}{n+1}\right)}, \\ F_n &= x_n - e^{\cos\left(\frac{x_{n-1}+x_n}{n+1}\right)}, \quad i = 2, 3, \dots, n-1. \end{aligned}$$

Table 1: Initial points

Tables (2-4) above reported the numerical results of the two methods, where 'ITER' and 'TIME' stand for the number of iterations and the CPU time (in seconds), respectively, while  $\|F_k\|$  is the norm of the residual at the stopping point. From the Tables, HDDPM and IDFDD methods attempt to solve the problem (1), but it is clear that the HDDPM method

outperforms the IDFDD method. In particular, the HDDPM method considerably outperforms the IDFDD for almost all the tested problems, as it has the least iteration and CPU time than the IDFDD method. Due to the contribution of the computation of correction parameter at each iteration. Thus, the proposed method successfully solves the large-scale system of nonlinear equations.

Fig. 1. Performance profile with respect to the number of iterations

Fig. 2: Performance profile with respect to the CPU time (in second)

Using the performance profile of Dolan and Moré (Dolan & Moré, 2009), we generate Figures 1 and 2 to show the performance and efficiency of each of the three methods. That is, for each method, we plot the fraction  $P(\tau)$  of the problems for which the method is within a factor  $\tau$  of the best time. Figures 1 and 2 show that the curves corresponding to the HDDPM method stay above the other curve representing the IDFDD method. This indicates that the proposed method outperforms the compared method in terms of fewer iterations and CPU time (in second), and hence, it is the most efficient. Finally, it is clear from both Figures that our method effectively solves the large-scale nonlinear system of equations.

### CONCLUSION

Hybridization of double direction method for solving system of nonlinear equations via Picard-Mann hybrid iterative process in Safeer (2013) is presented in this work. This was achieved by modifying the method in Halilu and Waziri (2018) using the correction parameter. The proposed method is an entirely derivative-free iterative method, which is why

it is more efficient in solving large-scale problems. Numerical comparisons have been made using a set of large-scale test problems. In addition, Table (2-4) and Fig. (1-2) have shown that the proposed method is very efficient because it has the least iteration and CPU time compared to the IDFDD method. In future research, the idea proposed in this scheme will be applied to solve the monotone nonlinear equations with application in compressive sensing.
