## **ABSTRACT**

Calcium carbonate ( $CaCO_3$ ) is an effective material for surface modification in  $TiO_2$ -based dye-sensitized solar cells (DSSCs). Its higher conduction band position compared to  $TiO_2$  helps reduce electron recombination rates, and its elevated isoelectric point promotes increased dye adsorption. It is crucial to control the thickness of the  $CaCO_3$  layer to less than 3-10 nm, as tunneling phenomena cannot occur when the insulating layer exceeds 10 nm in thickness. In this study, the  $CaCO_3$  layer was deposited using the spin-coating method. Additionally, in two samples, the second  $TiCl_4$  treatment was omitted during DSSC preparation to assess its impact on the photovoltaic properties. The results indicate that while the deposition of  $CaCO_3$  enhances the photocurrent of the DSSCs, it simultaneously reduces the fill factor. However, applying the  $TiCl_4$  treatment both before and after  $CaCO_3$  deposition improves the fill factor, leading to greater efficiency compared to the untreated samples. Specifically, sample TT3CT achieved an efficiency of 7.98%, while the neat sample reached 7.58% efficiency.

Keywords: DSSC, Surface Modification, Recombination Barrier Layer, Calcium Carbonate

## I. INTRODUCTION

Traditional and non-renewable energy sources like coal, oil, and natural gas provide a significant portion of energy demands. Burning fuels releases carbon dioxide into the atmosphere, contributing to various environmental problems (1). Therefore, renewable energy sources like wind and solar power are suitable alternatives to be used as solutions for global energy demands (2). Converting the sunlight to electricity, directly, by photovoltaic solar cells is one of the most efficient approaches [3, 4]. Dye-sensitized solar cells (DSSCs) which were proposed in 1991 by Gratzel and O'Regan, are popular for their cost-effective fabrication and potential for flexibility in photovoltaic devices [5, 6]. The photoanode is a key component of a DSSC, composed of a nanostructured oxide semiconductor, typically TiO<sub>2</sub> (7). Although TiO<sub>2</sub> offers many merits for this application, the electrons injected into its conduction band can be captured by oxidizing species in the electrolyte or by oxidized dye molecules. This interaction leads to a high rate of electron recombination, which results in lower current output. Simple methods, such as acid treatment or depositing blocking layers, can effectively reduce this recombination rate [8–10].

Metal oxides or carbonates such as MgO, Al<sub>2</sub>O<sub>3</sub>, ZnO, and CaCO<sub>3</sub> can be deposited between TiO<sub>2</sub> and the electrolyte, leading to a decrease in the recombination rate [9, 11, 12]. Optimizing the thickness of the blocking layer is crucial. While this layer should block recombination, it should not prevent electron injection from dye to TiO<sub>2</sub> (9). CaCO<sub>3</sub> is one of the most abundant minerals and has many desirable properties in various applications. Calcite with a rhombohedral structure and an indirect bandgap of 6.0 eV is the most stable polymorph of CaCO<sub>3</sub> [13–15]. In addition, calcite has a higher isoelectric point than anatase, therefore, it has more basicity and can absorb more dye. The enhancement of dye absorption results in more photocurrent and efficiency (16). K. Tehare et al. deposited four blocking layer materials and found that MgO-coated and CaCO<sub>3</sub>-coated TiO<sub>2</sub> had the highest efficiencies, increasing from 1.97% for pure TiO<sub>2</sub> to 6.05% and 4.25%, respectively (17). Lee et al. enhanced the efficiency of DSSCs from 7.8% to 9.7% by depositing a 3.5 nm thick layer of CaCO<sub>3</sub> (18). Park et al. enhanced

dye-sensitized solar cell efficiency by using CaCO<sub>3</sub> surface modification and nitrogen doping in TiO<sub>2</sub> photoanodes, achieving 7.46% and 9.03% efficiencies, respectively (11).

Our research aims to develop a cost-effective method for depositing an ultra-thin layer of  $CaCO_3$  on  $TiO_2$  and to explore replacing  $CaCO_3$  with  $TiCl_4$  treatment. We also investigated the photovoltaic properties of DSSCs using both methods. The goal is to compare the performance of  $TiO_2$ -based DSSCs with the  $CaCO_3$  layer and assess the effects of  $TiCl_4$  treatment.

#### II. MATERIALS AND METHODS

## Synthesis of TiO<sub>2</sub> nanoparticles

TiO<sub>2</sub> nanoparticles with particle size of 15-30 nm were synthesized using a combination of solvothermal and solgel techniques, following a previously established procedure (19). For this purpose, titanium tetraisopropoxide (TTIP) (97% purity, Sigma-Aldrich, UK) was used as a Ti precursor.

## • Preparation of photoanode electrodes

FTO-coated glass substrates (Solaronix, Switzerland) were washed with detergent. After rinsing with deionized water, a compact TiO<sub>2</sub> layer was deposited using a 0.04 M TiCl<sub>4</sub> solution and heat-treated at 450 °C for 30 minutes. TiO<sub>2</sub> paste was then spin-coated onto the substrate, followed by annealing at 400 °C for 2 hours. The spin-coating parameters were set to achieve a thickness of 35 μm, which was optimized in the previous work (20).

To deposit the ultra-thin layer of  $CaCO_3$ , solutions of  $Ca(NO_3)_2$  and NaOH were prepared using a 1:1 mixture of deionized water and ethanol. Three drops of the  $Ca(NO_3)_2$  and NaOH solutions were placed on the surface of the photoanodes and then spin-coated at a speed of 5000 rpm for 2 minutes each. The number of cycles for  $CaCO_3$  deposition for each sample can be found in Table I. Next, a 0.5 cm  $\times$  0.5 cm square of the film was trimmed. A 0.5 mM dye solution (ruthenium 535-bisTBA; Solaronix, Switzerland) was prepared in ethanol, and the photoanode electrodes were immersed in this solution for 21 hours in the dark. Afterward, the dye-loaded photoanodes were rinsed with ethanol and used for photovoltaic measurements.

To further characterize the formation of  $CaCO_3$ ,  $CaCO_3$  powders were synthesized by reacting  $Ca(NO_3)_2$  and NaOH solutions without a  $TiO_2$  substrate. These powders were treated using the same method employed for the  $CaCO_3$  coating on  $TiO_2$  surfaces.

Sample TT underwent post-treatment with a  $0.01~M~TiCl_4$  solution after the deposition of the  $TiO_2$  nanoporous film. Similarly, samples TT1CT and TT3CT were treated using the same method, both before and after  $CaCO_3$  deposition. All three samples were then annealed at  $450~^{\circ}C$  for 30 minutes in an air atmosphere after each treatment step.

## • Fabrication of DSSCs

The counter electrode was prepared by drop-coating a solution of H<sub>2</sub>PtCl<sub>6</sub> onto a cleaned FTO substrate with a 1 mm hole for electrolyte injection. After drying at 60°C, it underwent heat treatment at 450°C for 30 minutes. The dye-soaked photoanode and Pt-coated counter electrode were sandwiched using Surlyn film (SX 1170-60, Solaronix, Switzerland). Finally, an iodine-based electrolyte was injected using a vacuum. Fig. 1 shows the schematic of the photoanode layers arrangement (a) sample TT, (b) samples T1C and T3C, and (c) samples TT1CT and TT3CT.

Table 1: Characteristics of CaCO<sub>3</sub>-deposited on TiO<sub>2</sub> DSSCs

Sample	Cycles of CaCO <sub>3</sub> deposition	Photoanode layers arrangement
TT	-	TiO <sub>2</sub> + TiCl <sub>4</sub> treatment
T1C	1	TiO <sub>2</sub> + CaCO <sub>3</sub> layer (1 Cycle)
T3C	3	TiO <sub>2</sub> + CaCO <sub>3</sub> layer (3 Cycles)
TT1CT	1	TiO <sub>2</sub> + TiCl <sub>4</sub> treatment + CaCO <sub>3</sub> layer (1 Cycle) + TiCl <sub>4</sub> treatment
TT3CT	3	TiO <sub>2</sub> + TiCl <sub>4</sub> treatment + CaCO <sub>3</sub> layer (3 Cycles) + TiCl <sub>4</sub> treatment

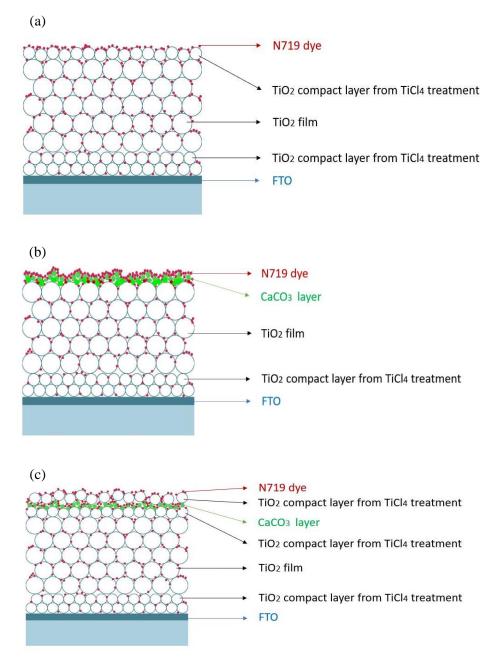

Fig. 1: Schematic of different structures of photoanode electrodes: (a) TT, (b) T1C and T3C, (c) TT1CT and TT3CT.

## • Characterization and measurements

The morphology of the synthesized samples and photoanodes was examined using a Mira-III field emission scanning electron microscope (FE-SEM) from TESCAN, Czech Republic. The crystal structures of TiO<sub>2</sub> and CaCO<sub>3</sub> were analyzed via X-ray diffraction (XRD) with an X'pert Pro MPD diffractometer from PANalytical, Germany, over a 2 $\theta$  range of 10° to 90° (Cu K $\alpha$ ,  $\lambda$  = 1.5406 Å). Thermogravimetric analysis (TGA) of CaCO<sub>3</sub> was conducted in a nitrogen atmosphere at a heating rate of 5 °C/min using a Mettler Toledo system. The amount of dye adsorbed on the photoanodes was measured with a UV-Vis spectrophotometer (6705 JENWAY, UK) in a 0.1 M NaOH solution. Photovoltaic metrics of the DSSCs were evaluated using a Zahner CIMPA-pcs solar simulator under standard conditions (irradiance of 100 mW/cm², AM 1.5, and a scan rate of 50 mV/s).

# III. RESULTS, DISCUSSION, AND CONCLUSION

## · Morphology and microstructure

Fig. 2 shows the FE-SEM image of the surface of the TiO<sub>2</sub> nanoporous film. The image illustrates that the TiO<sub>2</sub> nanoparticles range between 10-30 nm and have spherical morphology. The nanoparticles of TiO<sub>2</sub> have agglomerated to form TiO<sub>2</sub> nanoporous film. Since the CaCO<sub>3</sub> layer was ultra-thin, the FE-SEM and EDS analyses could not show the morphology of the CaCO<sub>3</sub> layer. Therefore, to characterize the CaCO<sub>3</sub> particles, the mentioned precursors were mixed with 10 times more concentration without TiO<sub>2</sub> film as the substrate. Fig. 3 depicts the FE-SEM image of the CaCO<sub>3</sub>, which was synthesized by this method. Second, the CaCO<sub>3</sub> layer was deposited on the surface of the TiO<sub>2</sub> substrate, using different spin-coating parameters and more cycles of depositing, followed by annealing at 450 °C for 30 min, just to characterize the CaCO<sub>3</sub> layer. Fig. 4 (a) illustrates the surface of the CaCO<sub>3</sub> thick layer, and Fig.4 (b) is related to the cross-section of the layer. As shown in Fig. 4, CaCO<sub>3</sub> particles exhibit rhombohedral morphology with particle sizes ranging between 300-600 nm.

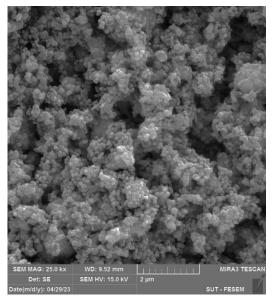

Fig. 2: FE-SEM image of TiO<sub>2</sub> nanoporous film.

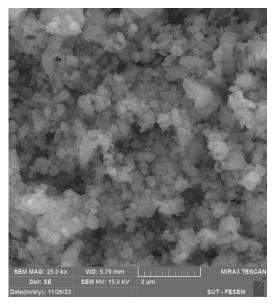

Fig. 3: FE-SEM of CaCO<sub>3</sub> particles.

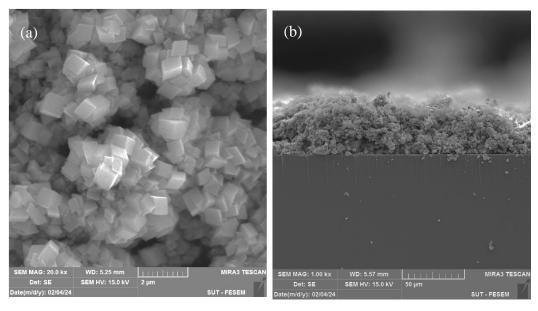

Fig.4: FE-SEM images of the  $CaCO_3$  layer on the surface of the  $TiO_2$  nanoporous film: (a) surface view and (b) cross-sectional view.

# • Crystal structure

The XRD technique was employed to analyze the crystal phase and structure of the synthesized materials. As demonstrated in Fig. 5, the pure anatase phase of  $TiO_2$  was synthesized, and the most intense peak observed at  $2\theta = 25.32^{\circ}$ , which matches card number 21-1272 in the JCPDS database.

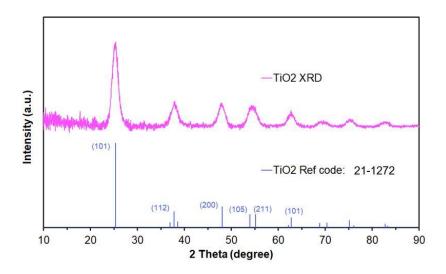

Fig. 5. XRD pattern of anatase-TiO<sub>2</sub> nanoparticles.

Additionally, Fig. 6 shows that the calcite phase of the  $CaCO_3$  was synthesized using the mentioned approach. The most intense peak appears at  $2\theta = 29.39^{\circ}$ . All other peaks are fully aligned with the card number 05-0586 in the JCPDS database.

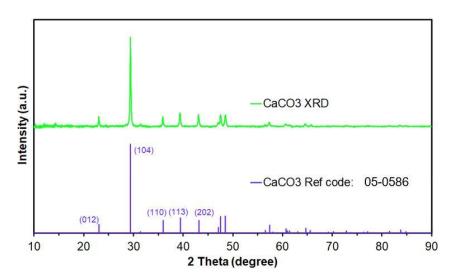

Fig. 6. XRD pattern of CaCO<sub>3</sub> particles.

## • Thermogravimetric analysis

The thermal behavior of  $CaCO_3$  powder was investigated by thermogravimetric analysis. As exhibited in Fig. 7, the TGA curve has 3 different steps. Step 1 is related to removing water from amorphous  $CaCO_3$ , occurring from room temperature to approximately 230 °C. The second step, which happens from 230 °C to 450 °C, is attributed to the loss of structural water in crystalline  $CaCO_3$ . The decomposition of  $CaCO_3$  to  $CaCO_3$  and  $CaCO_3$  shows a significant weight loss of 44%, starting from 550 °C. Therefore, after  $CaCO_3$  deposition, the annealing temperature was chosen at 450 °C to ensure structural water was removed and  $CaCO_3$  was kept in the system.

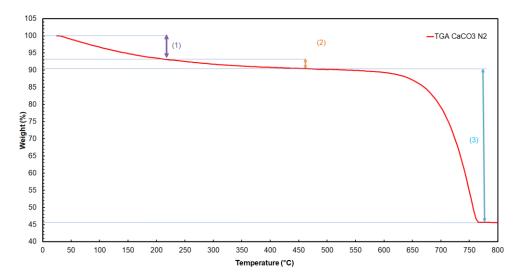

Fig. 7: TGA curve of synthesized CaCO<sub>3</sub> particles.

# • Diffuse reflectance spectroscopy analysis

The optical properties of the synthesized CaCO<sub>3</sub> and TiO<sub>2</sub> powders were examined using diffuse reflectance spectroscopy analysis. The band gap of CaCO<sub>3</sub> and TiO<sub>2</sub> powders, determined using the Tauc model, is presented in Fig. 8. The calculated band gap of TiO<sub>2</sub> is 3.15 eV and this is 4.96 eV for CaCO<sub>3</sub>. The result shows that CaCO<sub>3</sub> can role as insulating layer on the surface of TiO<sub>2</sub> nanoporous film.

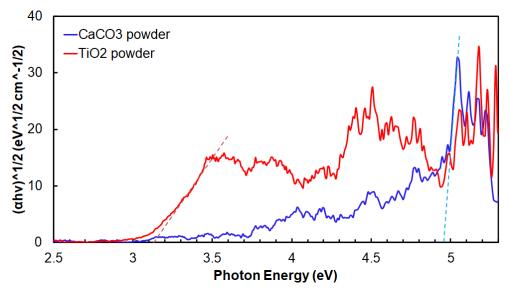

Fig. 8: Tuac plot of CaCO3 and TiO2 powders.

# Photovoltaic performance of DSSCs

Fig. 9 illustrates the photovoltaic properties DSSCs, highlighting parameters such as open circuit voltage (Voc), short circuit current (Jsc), power conversion efficiency ( $\eta$ ), and fill factor (FF). These parameters are summarized in Table 2. The baseline for comparison is the pure TiO<sub>2</sub> DSSC (denoted as TT), which has a Jsc of 16.28 mA/cm², a Voc of 0.74 V, a fill factor of 0.63, and an overall efficiency of 7.58%. By depositing CaCO<sub>3</sub>, the photocurrent of the samples increased, except for TT1CT. The enhancement in photocurrent is due to the blocking of electron recombination and enhanced dye adsorption by depositing CaCO<sub>3</sub> ultra-thin layer. Significant improvements in

Jsc were observed for samples T1C and T3C; however, both Voc and fill factor decreased in these cases. Consequently, the overall efficiencies for T1C and T3C dropped to 7.14% and 5.27%, respectively. As indicated in Table 2, the series resistance increased in these samples, leading to a reduction in the fill factor from 0.63 to 0.46 for T1C and 0.43 for T3C. This decrease in fill factor is attributed to the omission of the TiCl<sub>4</sub> treatment, which typically enhances the fill factor of DSSCs by improving surface roughness and layer interaction. A comparison between the fill factors of TT1CT and TT3CT with T1C and T3C demonstrates the significant impact of TiCl<sub>4</sub> treatment on DSSCs. The fill factors reached 0.66 and 0.64 for TT1CT and TT3CT, respectively. Although Jsc decreased compared to T1C and T3C, the overall efficiencies of TT1CT and TT3CT were higher than those of the other samples due to their optimization of Jsc, Voc, and fill factor. TT3CT shows the best performance among other samples with an enhancement of 5% in efficiency compared to TT.

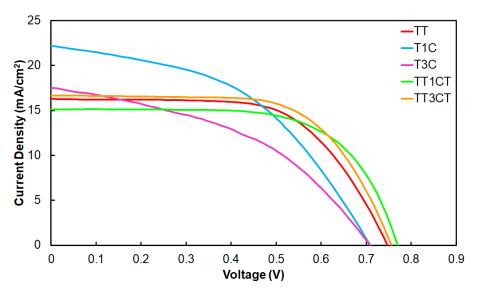

Fig. 9: J-V curves of DSSCs.

Sample	$J_{SC}$	V <sub>OC</sub>	FF	η
1	(mA/cm <sup>2</sup> )	(V)	(%)	(%)
TT	16.28	0.74	0.63	7.58
T1C	22.20	0.70	0.46	7.14
T3C	17.53	0.70	0.43	5.27
TT1CT	15.13	0.76	0.66	7.59
TT3CT	16.64	0.75	0.64	7.98

Table 2: Photovoltaic parameters of DSSCs

The measurement of dye absorption for TT, T1C, and T3C, which is shown in Fig. 10 and summarized in Table 3, indicates that the amount of absorbed dye increased with the addition of CaCO<sub>3</sub>. This was expected, as CaCO<sub>3</sub> has a higher isoelectric point and can interact with the carboxylic acid groups of the dye molecules.

Specifically, the dye adsorption increased from 4.98 10<sup>-8</sup> mol/cm<sup>2</sup> to 13.80 10<sup>-8</sup> mol/cm<sup>2</sup> for T1C and 19.53 10<sup>-8</sup> mol/cm<sup>2</sup> for T3C. A greater amount of dye absorption can enhance photocurrent generation by improving light harvesting within the system. However, a comparison of the results from Table 2 and Table 3 shows that this

increase in absorption alone is insufficient for achieving greater efficiency. Other photovoltaic parameters, such as the fill factor, are also critical for reaching higher efficiency. For instance, T1C, despite having a significantly higher dye adsorption of  $19.53 \times 10^{-8}$  mol/cm², demonstrates a much lower efficiency of 5.78%. This suggests that omitting the TiCl<sub>4</sub> treatment negatively affects electron transport and increases resistance in the system, ultimately overshadowing the advantages of higher dye absorption.

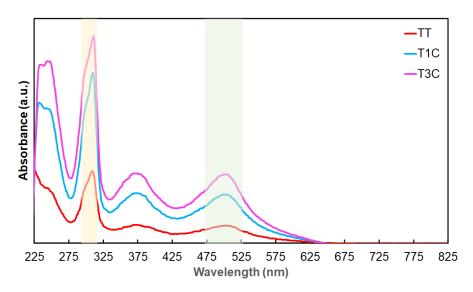

Fig. 10: UV-vis spectroscopy of photoanodes with N719 dye.

Sample	Dye adsorption (mol/cm <sup>2</sup> ) × 10 <sup>-8</sup>
TT	4.98
T1C	13.80
T3C	19.53

Table 3: The amount of dye adsorption

## Conclusion

An ultra-thin layer of CaCO<sub>3</sub> can enhance the photocurrent of DSSCs by preventing electron recombination and increasing dye absorption. However, using CaCO<sub>3</sub> alone is not a sufficient substitute for TiCl<sub>4</sub> treatment, as omitting TiCl<sub>4</sub> results in a lower fill factor for the system. Samples that underwent both TiCl<sub>4</sub> treatment and CaCO<sub>3</sub> deposition exhibited higher photocurrent, fill factor, and overall efficiency. Nonetheless, their photocurrent was still lower than that of samples with only CaCO<sub>3</sub> deposition. Notably, sample TT3CT demonstrated a 5% increase in efficiency compared to the neat sample TT.
