ABSTRACT

Cobalt ferrite nano-powder have been obtained through a hydrothermal method with 2:1 molar ratio of Fe:Co without using any surfactant. X-Ray Diffraction (XRD) and Scanning Electron Microscopy (SEM) were used to consider the structural and morphological properties of CoFe₂O₄ nano-particles. Also, EDAX spectroscopy applied to evaluate the chemical composition. Results demonstrated that 15 hr hydrothermal processing was enough. In the hydrothermal period of reaction more than 15 hr (21 hr) Fe $_2\rm O_3$ sub-phase was identified which this could be due to instability of CoFe $_2$ O₄ at supercritical condition. The average particle size and the percentage of crystallinity for single phase sample were calculated 34.7 nm and 98%, respectively.

Keyword: Nano-powder; Hydrothermal; Cobalt Ferrite; Crystallinity; Sub-phase.

1. INTRODUCTION

In the Last decades, synthesis of bimetallic spinel netic materials, cobalt ferrite with high coercivity, high ferrites has attracted attention $[1]$. Among this magmagnetocrystalline anisotropy, large magneto-optical coefficient [2], moderate saturation magnetization, high chemical stability [3], supported wide range of applications. From spinel ferrites, CoF_2O_4 , MnFe_2O_4 and high chemical stability [3], supported wide range of ap- $NiFe₂O₄$ have been investigated as potential $T2$ "con NiFe₂O₄ have been investigated as potential T2 "contrast agents [4]". Magnetic properties of CoFe₂O₄ subjected this to be applied in magnetic resonance imagjected this to be applied in magnetic resonance imagining (MRI) as contrast agents [5]. In additional, the ferrites were shown a good photo catalytic activity in

nation with other metals such as Ag. Cobalt ferrite was UV-Visible range and antimicrobial activity in combishown effective reduction of $CO₂$ to methanol [6].

Various synthesis methods have been developed to produce ferrite nano-particles such as Solvothermal [7-10], Microwave [11, 12], Coprecipitation [13, 14], Hydrolysis [15], Complexometery [16], Liquid-phase method $[17]$, and Auto-combustion $[18-20]$. Among these methods, hydrothermal synthesis requires neither sophisticated processing nor high processing tempera-
ture [10].

The main purpose of this work was to investigate a

no-particle without using any surfactant, stabilizer or line, small size and uniform shape cobalt ferrite nasimple hydrothermal route to produce a good crystalcapping agents as additive or high pressure and tem-
perature conditions.

This method is very attractive for higher scale and continuous product $[21, 22]$. In this work, fine CoFe_2O_4 nano-particles have been synthesized with a simple hydrothermal technique. Characterization of nano-particles showed decomposition of CoFe_2O_4 to sub-phases after 21 hr reaction time.

EXPERIMENTAL 2.

Materials 2.1.

Iron (III) nitrate nona-hydrate (Merck $99-101\%$), cobalt (II) nitrate hexa-hydrate (Merck 99%) and Sodium hydroxide (NaOH) used as chemical agents. All solutions prepared with deionized water.

2.2. Synthesize of CoFe₂O₄

Nano-particles synthesis without any surfactant or need to pressure monitoring carried out as follow: cobalt and iron solutions prepared by dissolving of 1.21 g cobalt nitrate in 250 mL deionized water and 3.36 g iron nitrate in 250 mL deionized water, cipitant agent and based on the nucleation theory respectively. 500 mL of NaOH (4M) used as pre-[23, 24], pH maintained above 11.5 with an aqueous 4 M solution of NaOH. Metal solutions were mixed tion under stirring. The solution mixed and heated for and immediately added to the boiling NaOH soluclave, sealed and heated for 15 and 21 hours at 180° C. 4 hours at 80 $^{\circ}$ C and then transferred to a simple auto-After hydrothermal reaction time, autoclave took out and remained until cooled to room temperature. Solid product collected on a filter and washed with absolute acted materials. Obtained powders prepared by 15 and ethanol and water several times to remove any unre-21 hr hydrothermal reaction dried with an electrical oven at 80 $^{\circ}$ C for 4 hours and then calcined in 600 $^{\circ}$ C for 2 hours and were denoted as S1 and S2, respectively.

2.3. Characterization process

X-ray diffraction (XRD) pattern was recorded by a "Philips X'pert", using Cu K α radiation at 40 kv and scope was used to characterize the morphologies and 30 mA. A "Philips $XL-30$ " scanning electron micromicrostructures of the samples.

3. RESULTS AND DISCUSSION

no-powders have been shown in Figure 1. All the X-ray powder diffraction patterns of calcined napeaks in plot of S1 were well matched with JCPDS $(No. 22-1086)$ card, so this sample was single phase and only contain CoFe_2O_4 as shown in Figure 1-S1. The unmatched peaks seen in S2 X-ray plot (Figure 1-S2) return to $Fe₂O₃$ presents as sub-phase. The av erage crystallite sizes calculated by using Scherrer's formula (Eq. 1) from 2theta positions from 20 to 80:

$$
d = 0.9\lambda / \beta \cos \theta \tag{Eq. 1}
$$

	Composition	Crystalline structure	Mean particle size of $CoFe2O4$ (nm)	Crystalline percent of CoFe ₂ O ₄ (%)	Lattice parameter (\AA)	Unit cell volume $(\AA)^3$
S ₁	CoFe ₂ O ₄	Cubic spinel	14	98	8.36	583.27
S ₂	CoFe ₂ O ₄	Cubic spinel	22	86.07	8.35	585.18
	Fe, O,	Rhombohedral	Not calculated	Not calculated	Not calculated	Not calculated

Table 1: Qualitative and quantitative extracted data from X-ray diffraction.

Where d is the grain size, β is half-intensity width of the relevant diffraction; λ is X-ray wavelength and θ is the diffraction angle.

The increase of particle size by increasing reaction time was obtained and approved by calculation from X-ray data and shows good crystalline percent about 98% for S1 from ratio of net area to total area.

Appearing a shift (from standard peaks) to the right ably corresponded to a decrease in lattice parameter position is clearly visible in both spectra. That's probdue to occurrence of some strain or elimination of some lattice defects and strains [25]. For investigation of this guess the lattice parameters were calculated by Brag's formula (Eq. 2) and report in Table 1.

$$
a = (h^2 + k^2 + l^2)^{1/2}
$$
 (Eq. 2)

Where h , k , and l is Miller indices and a is the lattice parameter.

As seen from calculated data, lattice parameters were in good agreement with 8.39 Å, lattice parameters for bulk CoFe_2O_4 , but in review of some same were in good agreement with 8.39 Å, lattice paramliteratures [26] that no-one faced with this shift phenomena in their XRD plots. At last, also equipment error's factor may be involved in this case.

Peak intensity decrease seen in Figure 1-S1. It seems in contrast with increasing in crystallinity in sample

Table 2: EDAX ZAF (Standard less) Element Normal-
ized for S1 and S2.

S.	Element	Wt(%)	At $(\%)$
S ₁	FeK	62.00	63.26
	CoK	38.00	36.74
S ₂	FeK.	61.72	62.98
	CoK	38.28	37.02

S1 reported in Table 1 but considering the presents of sub-phase justified.

Yanez-Vilar et al. [8] reports the synthesis of single-phase CoFe_2O_4 in solvothermal conditions (by Yanez-Vilar et al. [8] reports the synthesis of sinhexanole and benzyl alcohol) in 180 $^{\circ}$ C for 24 and 48 hours. Also Zaho and coworkers [10], studied the reaction time (from 10 to 360 min) and concluded that in hydrothermal method, period of reaction has little influence on the size and morphology of particles but any data presented in their paper prove this claim. In this work we observed that if reaction time increases to 21 h, the sub-phase $Fe₂O₃$ is formed. This means that $\text{CoFe}_{2}\text{O}_{4}$ prepared in in the hydrothermal procedure (15 hour) is unstable and decompose to $Fe₂O₃$. $Co²⁺$ cause this ion in washing step with water and alcohol ions in qualitative analysis have not been observed beis dissolved and removed from the product. Presents stracted in Table 2. The SEM images of S1 and S2 presented in Figures 2 and 3, respectively. Both sample of Co and Fe confirm by EDAX data series that abstracted in Table 2. The SEM images of S1 and S2 preof Co and Fe confirm by EDAX data series that abimages shows the uniform spherical morphology. The value of particle size obtained from SEM images for S1 and S2 samples are 29 and 34 nm, respectively, lated from X-ray peaks by Scherrer's equation. The which this result confirms the crystallite size calcu-SEM images for both samples shows that the particles

Figure 2: SEM imagining of S1 (15 hr hydrothermal sample).

Figure 3: SEM imagining of S2 (21 hr hydrothermal sample).

dispersed uniformly, but agglomerated to some extent due to the interaction between magnetic nanoparticles.

CONCLUSIONS 4.

cessfully with hydrothermal route using the sodium Cobalt ferrite nano-particles were produced suchydroxide as precipitant agent. Results could be drawn as follows: X-ray pattern's shows the presents of the sub-phase in 21 hr hydrothermal processing. We guess that obtained $\text{CoFe}_{2}\text{O}_{4}$ after 15 hr hydrothermal con that obtained CoFe₂O₄ after 15 hr hydrothermal condition was instable and a slight disintegrate to Fe₂O₃ carried out. The obtained CoFe_2O_4 nano-particles in 15 and 21 hours hydrothermal process, was fine in size about 14 and 22 nm for main phase, respectively.
